(Received 19 January 2005; after final revision 28 March 2007; accepted 24 May 2007)

In this paper, a convexity for the edge set of a graph $G = (V, E)$ is defined. It is a matroid of rank $p - 1$ where $|V(G)| = p$ and its arity is not in general two. The classical convex invariants are also evaluated.

Key Words: Cyclic convexity; edgematroid; convexity parameters

1. INTRODUCTION

For the vertex set of a connected graph $G = (V, E)$ different types of convexities have been studied. All are path convexities and are induced by suitable interval operators, hence they are called interval convexity spaces. The arity of such convexity spaces is two [7]. Most widely studied are geodesic convexity and induced path (minimal path) convexity. Van de vel [7] has given a detailed account of combinatorial convexity theory in graphs and other discrete structures. Some other contributions on these lines are [1] to [6].

In this paper, we have two aims:

1. To extend the convexity notions to the edge set of a graph.
2. To study the properties of convexity spaces of arity greater than 2.

All basic graph theoretic and convex theoretic concepts are from [7].

In this paper we define cyclic convexity for the edge set of a graph. It is a matroid of rank $p - 1$. Classical convex invariants-Helly number, Radon number, Caratheodory number and exchange number are also evaluated.

2. CYCLIC CONVEXITY

Definition 1 — [7] Let X be a non-empty set. A collection \mathcal{C} of subsets of X is called a convexity on X if \mathcal{C} is closed for intersections and for chained unions. The pair (X, \mathcal{C}) is called a convexity space.

Members of \mathcal{C} are called convex sets. For any set $S \subseteq X$ the convex hull of S is the smallest convex set containing S and is denoted by $Co(S)$.

Definition 2 — [7] A convexity space (X, \mathcal{C}) is of arity $< n$ if its convexity is determined by n -polytopes.

That is, a subset C of X is convex if and only if $Co(F) \subseteq C$ for each subset F of X of cardinality at most n .

Let G be a graph with edge set E . Let \mathcal{C} denote the collection of cycles and \mathcal{C}_c denote the collection of chordless cycles of G and let $\mathcal{E} = \{S \subseteq E : \mathcal{C} \in \mathcal{C} \text{ and } |C \cap S| > |C| - 1 \text{ implies } C \subseteq S\}$ and $\mathcal{E}_c = \{S \subseteq E : C \in \mathcal{C}_c \text{ and } |C \cap S| > |C| - 1 \text{ implies } C \subseteq S\}$.

Lemma 1 — $\mathcal{E} = \mathcal{E}_c$.

PROOF: It is obvious that $\mathcal{E} \subseteq \mathcal{E}_c$. Conversely, suppose that $S \in \mathcal{E}_c$ and let C be the cycle of length k such that $|C \cap S| = |C|$, then it is clear that $C \subseteq S$. If $|C \cap S| = |C| - 1$, suppose that $C \cap S = C - \{e\}$ and C is not induced. Otherwise $C \in \mathcal{C}_c$ and $C \subseteq S$ is clear. Assume that all cycles C' with $|C'| < |C|$ and with $|C' \cap S| > |C'| - 1$, $C' \subseteq S$. Now, any chord e' of C either with some path of $C - \{e\}$ forms a cycle C' of length $k' < k$ with $|C' \cap S| > |C'| - 1$, which implies that $e' \in S$. Thus, all chords of C are in S . The edge e belongs to some chordless cycle C'' induced by some of the vertices of C with $|C''| < |C|$. Also $|C'' \cap S| > |C''| - 1 \Rightarrow C'' \subseteq S \Rightarrow e \in S \Rightarrow C \subseteq S \Rightarrow S \in \mathcal{E}$. Hence, $\mathcal{E}_c \subseteq \mathcal{E}$.

Definition 3 — The collection \mathcal{E} forms a convexity on E and is called the cyclic convexity.

Note: This convexity space is denoted by (G, \mathcal{E}) .

In other words, $S \subseteq E$ is convex if and only if for any cycle C in G , $C \subseteq S$ whenever $C - e \subseteq S$ for any $e \in C$. For any $S \subseteq E$, $Co(S_0) = \{e' : e' \in S_0 \text{ or } C - e' \subseteq S_0 \text{ for some cycle } C \text{ in } G\}$.

Examples —

1. For a tree T every subset of $E(T)$ is trivially convex.
2. In the graph G .

Now, we shall consider a generalization of the notion of geodesic iteration number of an interval convexity space to a convexity space of arity greater than two.

Definition 4 — Let (X, \mathcal{C}) be a convexity space of arity n , $n > 2$ and $S \subseteq X$. The closure of S , denoted by \bar{S} is defined as $\bar{S} = \bigcup \{Co(F) : F \subseteq S, |F| < n\}$. S^m is recursively defined as, $S^0 = S$, $S^m = (\bar{S}^m)$. The smallest positive integer m such that $S^{m+1} = S^m$ is called the iteration number of S . The iteration number of (X, \mathcal{C}) is defined to be the maximum iteration number of $S \subseteq X$.

FIG. 1. $\{e_1, e_2, e_3\}$, $\{e_2, e_5, e_8\}$ are convex, but $\{e_5, e_6, e_8\}$ is not convex.

Lemma 2 — The iteration number of (G, E) is 1.

PROOF: Let $S \subset E$. It suffices to prove that $S^2 \subset S^*$. Let $e \in S^2$. Then, there is $C \in \mathcal{C}_e$ such that $C - \{e\} \subset S^1 = (S)$.

Let $e' \in C - \{e\}$. Then $E(C) - \{e, e'\}$ is convex. Hence $e' \in C_0(E(C) - \{e, e'\})$. Now, $e' \in S^1$ implies that there exist a cycle $C' \in \mathcal{C}_{e'}$ such that $C' - \{e'\} \subset S$. Then, $C - \{e'\} \cup C' - \{e'\}$ is a cycle $C'' \in \mathcal{C}$ such that $C'' - \{e\} \subset S$, which implies that $e \in S^*$. Thus $S^* = S^2$ and so the iteration number is 1.

Theorem 1 — The arity of (G, \mathcal{E}) is one if G is a tree and is one less than the size of a largest chordless cycle in G , otherwise.

PROOF: If G is a tree, then there is nothing to prove. Now, let k be the size of a largest chordless cycle C in G . It is clear that the arity is at most $k - 1$. On the other hand, let $S = E(C) - \{e\}$ for some edge e of C and suppose $S' \subset S$, $S' \neq S$. Then for any $C' \in \mathcal{C}_{e'}$, $|C' \cap S| < k - 2$. Therefore, $S' \in E$, but $S \notin E$. Thus, the arity is greater than $k - 2$ and so the arity of $(G, \mathcal{E}) = k - 1$.

Note: In literature, there are not many examples of convexity spaces of arity greater than two.

Definition 5 — [7] A convexity space X is a matroid if it satisfies the exchange law, for any convex set $C \subset X$ and $a, b \in X - C$, $a \in Co(C \cup \{b\})$ implies that $b \in Co(C \cup \{a\})$.

Definition 6 — An non empty set F of X is convexly independent if $x \notin Co(F - \{x\})$ for each $x \in F$.

Note: If X is a matroid, there exists a maximal independent subset of X called a basis and its cardinality, the rank.

Theorem 2 — If G is a connected graph of order p , then (G, E) is a matroid of rank $p - 1$.

PROOF: It follows that (G, \mathcal{E}) is a matroid, by the definition of cyclic convexity. Now, let T be a spanning tree of G and let $F = E(T)$ and let $e \in F$.

Claim — $e \in Co(F - \{e\})$.

$e \in Co(F - \{e\})$ implies that there is a cycle $C \in \mathcal{C}$ such that $C - \{e\} \subset F - \{e\}$ which implies $C \subset F$, a contradiction. Therefore, F is independent. Hence, rank of $(G, \mathcal{E}) > p - 1$. Now, if $|F| > p$ then F contains a cycle and hence it is convexly dependent. So, the rank is $p - 1$. \square

3. CONVEX INVARIANTS

The convex invariants of a convexity space X are defined as follows [7].

The Helly number of X is the smallest number n such that $\bigcap \{Co(F - \{a\}) : a \in F\} \neq \emptyset$ (that F is Helly (H —) dependent) for all $F \subset X$ with $|F| > n$.

The Radon number of X is the smallest number n such that each $F \subset X$ with $|F| > n$ can be partitioned into S_1 and S_2 such that $Co(S_1) \cap Co(S_2) \neq \emptyset$. (that is, F is Radon (R —) dependent).

The Caratheodory number of X is the smallest number n such that $Co(F) = \bigcup \{Co(F - \{a\}) : a \in F\}$ (that is, F is Caratheodory (C —) dependent) for all $F \subset X$ with $|F| > n$.

The exchange number of X is the smallest number n such that for $F \subset X$, $|F| > n$ and $p \in F$, $Co(F - \{p\}) \cup \{Co(F - \{a\}) : a \in F\} \neq \emptyset$ (that is, F is exchange (E —) dependent).

Theorem 3 — Let G be a connected graph of order p , then the Helly number of (G, E) ,

PROOF: Let T be a spanning tree of G and $F \subset E(T)$. We prove that F is Helly independent.

Suppose $\bigcap \{Co(F - \{e\}) : e \in F\} = \emptyset$. Let $e \in F$, $e \in Co(F - \{e\})$ and $e' \in F$. Then, there is a cycle C in G such that $C - e = F - \{e\}$.

Now, suppose that $e' \in \bigcap \{Co(F - \{e\}) : e \in F\}$ where $e' = uv$. Then $e' \in e$ for any $e \in F$. If $e_2 \in F$ then there exist cycles C_1 and C_2 in G such that $C_1 - e_1 = F - \{e_1\}$ and $C_2 - e_2 = F - \{e_2\}$. Then the cycle C comprising the paths $C_1 - e'$ and $C_2 - e'$ is in T which is a contradiction.

Hence $\bigcap \{Co(F - \{e\}) : e \in F\} \neq \emptyset$. So F is Helly independent. Therefore $h(G) \geq p - 1$.

Now, suppose $|F| > p$. Then F contains a cycle C in G . Then $e' \in Co(F - \{e\})$ for any $e' \in C$ and hence $e' \in Co(F - \{e\})$ for any $e \in F$, which implies that $C \subset \bigcap \{Co(F - \{e\}) : e \in F\}$. Therefore, F is Helly dependent and so $h(G) < p$. Thus, $h(G) = p - 1$.

Theorem 4 — The Caratheodory number of (G, E) is given by, $c(G) = 1$ if G is a tree and $c(G) = \text{Circ}(G) - 1$ otherwise, where $\text{Circ}(G)$, the circumference of G is the length of a largest cycle in

PROOF: If G is a tree, then every subset of E is convex. So for each $F \subset E$ with $|F| > 1$, we have $Co(F) = F = \bigcup \{F - \{a\} : a \in F\} = \bigcup \{Co(F - \{a\}) : a \in F\}$. Hence $c(G) = 1$.

Now, let C be a longest cycle of length k and $S = E(C)$. Let $C = a_1 - e_1 - a_2 - e_2 - \dots - a_k - e_k - a_1$, where a_i s are vertices and e_i s are edges. Let $S_i = S - \{e_i\}$, $i = 1, 2, \dots, k$.

Claim — S_i is C -independent.

Here $Co(S_i) = S$ because $|C \cap S_i| = |S_i| = |C| - 1$. We have $Co(S_i) = E(C) = S$. But $Co(S_i - e)$ for any S_i . Hence $S = Co(S_i) = \bigcup \{Co(S_i - e) : e \in S_i\}$. Therefore S_i is C -independent. So $c(G) > |S_i| = |S| - 1 = \text{Circ}(G) - 1 = k - 1$.

Now, if $F \subset E$, $|F| > k$ and if $e \in Co(F)$ then there is a cycle C in G such that $e \in C$ and $C - e \subset F$.

If $C - e \neq F$, there is an edge $e' \in F$ which is not in C . Then $C - e \subset F - e'$ and hence $e \in C = Co(C - e) \subset Co(F - e')$. Thus $Co(F) \subset \bigcup \{Co(F - e) : e \in F\}$.

If $C - e = F$ then $|C| = |F| + 1$, which is a contradiction because $Circ(G) = k$.

Theorem 5 — Let G be a connected graph of order p , then the Radon number of (G, E) , $r(G) = p - 1$.

Theorem 6 — Let G be a connected graph. The exchange number of (G, E) , $e(G) = 2$, if G is a tree or a cycle and is $\max\{Circ(G - v) : v \in G\}$, otherwise.

PROOF: *Case I* — Let G be a tree. Then every subset F of $E(G)$ is convex. If $|F| < 2$, let $F = \{e_1, e_2\}$. Then $F - \{e_1\}$ is not a subset of $F - \{e_2\}$. Hence F is E -independent. If $|F| > 3$, let $F = \{e_1, e_2, \dots, e_n, p\}$, $n > 2$. Then $Co(F - \{p\}) = F - \{p\} = \{e_1, e_2, \dots, e_n\} \subset \bigcup \{F - \{e_i\} : i = 1, 2, \dots, n\}$. So, $Co(F - \{p\}) \subset \bigcup \{F - \{e\} : e \neq p, e \in F\}$.

Case II — Let G be a cycle. Then either $F = E$ or F has no subset comprising a cycle. If $F = E$, $Co(F - \{e\}) = F$ for each $e \in F$. If $F \subset E$, since F has no subset comprising a cycle, each proper subset of F is convex, so that the proof is same as that of Case I. Thus, in both these cases $e(G) = 2$.

Case III — Let G be a graph having a cycle C and a vertex $v \notin C$.

Assume that C is a largest cycle such that there is a vertex $v \notin C$. Let $C = a_1 - e_1 - a_2 - e_2 - \dots - a_{n-1} - e_{n-1} - a_n - e_n - a_1$ where a_i 's are vertices and e_i 's are edges between a_i and a_{i+1} . Let e be any edge incident on v and let $S = \{e_1, e_2, \dots, e_{n-1}, e\}$. Then $e_n \in Co(S - e)$, but $e_n \notin Co(S - e_i)$ for $i \leq n$. Hence S is E -independent and $e(G) > n$. Now, if $S = \{e_1, e_2, \dots, e_m\}$, $m > n + 1$, let $e \in Co(S - e_i)$ for some i . Then there is a cycle C in G such that $e \in C$ and $C - e \subset S - e_i$. If $C - e = S - e_i$, $|C| = |S| > n + 1$, which is a contradiction. Hence there is some $e_j \in S - e_i$ such that $e_j \in C$ and so $e \in Co(S - e_j)$. Therefore, S is E -dependent and $e(G) < n + 1$. Thus $e(G) = n$.
